COSMOLOGY WITH AN EXTRA-DIMENSION

David Langlois
GReCO, Institut d'Astrophysique de Paris,

I present the main features of the brane cosmology scenario, according to which our universe is a self-gravitating brane embedded in a five-dimensional spacetime.

1 Introduction

The purpose of this contribution is to give an introduction to a new vision of extra-dimensions: the so-called "braneworld" picture. In this scenario, ordinary matter is trapped in a three-dimensional space, called 'brane', embedded in a higher dimensional space.

This idea must be contrasted with the traditional view of extra dimensions, the Kaluza-Klein picture, where matter fields live *everywhere* in *compact* extra dimensions. Any such higher dimensional field can be described, via a Fourier expansion, as an infinite collection of four-dimensional fields, the so-called Kaluza-Klein modes, with masses depending on the size of the extra-dimensions. Non-observation of Kaluza-Klein modes in colliders thus gives an upper bound on the size of the extra-dimension, typically

$$R \lesssim E_{max}^{-1}, \tag{1}$$

where E_{max} is the highest energy probed in colliders, i.e. $E_{max} \sim 1$ TeV today.

In the context of string theory, extra dimensions were promoted from an interesting curiosity to a theoretical necessity since superstring theory requires ten space-time dimensions to be consistent from the quantum point of view. Until recently, the six extra-dimensions were however hidden, or 'compactified', *à la* Kaluza-Klein. The new implementation of extra dimensions has emerged lately, notably with M-theory and the Horava-Witten model [1] which describes the low energy effective theory corresponding to the strong coupling limit of $E_8 \times E_8$ heterotic string theory. This model gives an eleven-dimensional bulk spacetime with 11-dimensional supergravity, the eleventh dimension being compactified via a Z_2 orbifold symmetry. The two fixed points

of the orbifold symmetry define two 10-dimensional spacetime boundaries, or 9-branes, on which the gauge groups are defined. A dimensional reduction of this model to five space-time dimensions yields a picture with two Z_2-symmetric three-branes separated in a fifth dimension, a picture somewhat similar to the framework of brane cosmology presented below.

2 Homogeneous cosmology in a brane-universe

The main motivation for exploring cosmology in models with extra-dimensions is that the signature of extra-dimensions might be accessible *only* at very high energies, i.e. in the very early universe. One would thus like to investigate what kind of relic imprints could be left and tested today via cosmological observations. The purpose of this section is to describe the homogeneous cosmology [2,3,4] of a self-gravitating brane-universe embedded in a five-dimensional spacetime.

Let us thus consider a five-dimensional spacetime with three-dimensional isotropy and homogeneity, which contains a three-brane representing our universe. It is convenient, but not necessary, to work in a Gaussian normal coordinate system based on our brane-universe. Due to the spacetime symmetries, the metric is then of the form

$$ds^2 = -n(t,y)^2 dt^2 + a(t,y)^2 \delta_{ij} dx^i dx^j + dy^2, \tag{2}$$

where we have assumed that our brane-universe is spatially flat (but this can be generalized very easily to hyperbolic or elliptic spaces). In these coordinates, our brane-universe is always located at $y = 0$.

The energy-momentum tensor can be decomposed into a bulk energy-momentum tensor, which will be assumed to vanish here, and a brane energy-momentum tensor, the latter being of the form

$$T^A_B = S^A_B \delta(y) = \{\rho_b, p_b, p_b, p_b, 0\}\delta(y), \tag{3}$$

with a delta function since ordinary matter is confined in the brane. ρ_b and P_b are respectively the total energy density and pressure in the brane and depend only on time. Allowing for a cosmological constant in the bulk, Λ, the five-dimensional Einstein equations read

$$G_{AB} + \Lambda g_{AB} = \kappa^2 T_{AB}. \tag{4}$$

In order to determine the influence of the brane on the curvature of space-time, it is useful to integrate Einstein's equations in the vicinity of the brane, which leads to the so-called junction conditions for the metric at the brane location $y = 0$. According to these junction conditions, the metric must be continuous and the jump of the extrinsic curvature tensor K_{AB} (related to the derivatives of the metric with respect to y) depends on the distributional energy-momentum tensor,

$$\left[K^A_B - K\delta^A_B\right] = \kappa^2 S^A_B, \tag{5}$$

where the brackets here denote the jump at the brane, i.e. $[Q] = Q_{\{y=0^+\}} - Q_{\{y=0^-\}}$, and the extrinsic curvature tensor is defined by $K_{AB} = h^C_A \nabla_C n_B$, n^A being the unit vector normal to the brane and $h_{AB} = g_{AB} - n_A n_B$ the induced metric. Assuming that the brane is mirror symmetric implies that the jump in the extrinsic curvature is twice its value on one side. Substituting the ansatz metric (2) in (5), one ends up with the two junction conditions [2]:

$$\left(\frac{n'}{n}\right)_{0^+} = \frac{\kappa^2}{6}\left(3p_b + 2\rho_b\right), \qquad \left(\frac{a'}{a}\right)_{0^+} = -\frac{\kappa^2}{6}\rho_b. \tag{6}$$

Solving explicitly [3] the Einstein equations (4) with the metric ansatz (2), one finds in particular that the geometry induced *in the brane* is governed by the equation

$$H_0^2 \equiv \frac{\dot{a}_0^2}{a_0^2} = \frac{\kappa^4}{36}\rho_b^2 + \frac{\Lambda}{6} + \frac{\mathcal{C}}{a^4}. \tag{7}$$

where the subscript '0' means evaluation at $y = 0$, i.e. $a_0(t) \equiv a(t, y = 0)$ and $\mathcal{C}$ is an integration constant. This equation is analogous to the (first) Friedmann equation, since it relates the Hubble parameter to the energy density, but is nevertheless different [the usual Friedmann equation reads $H^2 = (8\pi G/3)\rho$]. Its most remarkable feature is that the energy density of the brane enters quadratically on the right hand side in contrast with the standard four-dimensional Friedmann equation where the energy density enters linearly. Another consequence of the five-dimensional Einstein equations (4) is that the energy conservation equation is unchanged and still reads

$$\dot{\rho}_b + 3H(\rho_b + p_b) = 0. \tag{8}$$

In the simplest case where $\Lambda = 0$ and $\mathcal{C} = 0$, one can easily solve the above cosmological equations (7-8) for a perfect fluid with an equation of state $p_b = w\rho_b$ and w constant. One finds that the evolution of the scale factor is given by

$$a_0(t) \propto t^{\frac{1}{3(1+w)}}. \tag{9}$$

In the most interesting cases for cosmology, radiation and pressureless matter, one finds respectively $a \sim t^{1/4}$ (instead of the usual $a \sim t^{1/2}$) and $a \sim t^{1/3}$ (instead of $a \sim t^{2/3}$). Such behaviour is problematic because it cannot be reconciled with nucleosynthesis. Indeed, the nucleosynthesis scenario depends on the balance between the microphysical reaction rates and the expansion rate of the universe, and changing in a drastic way the evolution of the scale factor between nucleosynthesis and today modifies dramatically the predictions for the light element abundances.

The modified Friedmann law (7), with the ρ_b^2 term but without the bulk cosmological constant (and without the $\mathcal{C}$ term) was derived [2] just before a new model describing a flat (Minkowski) world with one extra-dimension was proposed by Randall and Sundrum[5]. The new ingredient was to endow our brane-world with a tension (constant energy density) and the five-dimensional bulk with a *negative* cosmological constant, the two being fine-tuned so that the effective four-dimensional Hubble parameter is zero in (7) (taking $\mathcal{C} = 0$). It turns out that such a set-up gives the usual four-dimensional gravity [5,6] (except on very small scales).

This suggested that the generalization of the Randall-Sundrum model to cosmology should be compatible with standard cosmology at small energy scales, as it was shown [7] speedily. If one wants to go beyond a Minkowski geometry and consider non trivial cosmology in the brane, one must assume that the total energy density in the brane, ρ_b, consists of two parts,

$$\rho_b = \sigma + \rho, \tag{10}$$

the tension σ, constant in time, and the usual cosmological energy density ρ. Substituting this decomposition into (7), one obtains

$$H^2 = \left(\frac{\kappa^4}{36}\sigma^2 + \frac{\Lambda}{6}\right) + \frac{\kappa^4}{18}\sigma\rho + \frac{\kappa^4}{36}\rho^2 + \frac{\mathcal{C}}{a^4}. \tag{11}$$

Let us now fine-tune the brane tension and the bulk cosmological constant so that the first term on the right hand side vanishes. The second term then becomes the dominant term if ρ is small enough and *one thus recovers the usual Friedmann equation at low energy*, with the identification

$$8\pi G = \frac{\kappa^4}{6}\sigma, \tag{12}$$

which also agrees with Newton's constant deduced from gravitational interaction between test masses. The third term on the right hand side of (11), quadratic in the energy density, provides

a *high-energy correction* to the Friedmann equation which becomes significant when the value of the energy density approaches the value of the tension σ and dominates at higher energy densities. In the very high energy regime, $\rho \gg \sigma$, one thus recovers the unconventional behaviour of (9) since the bulk cosmological constant becomes negligible. For an equation of state $p = w\rho$, with w constant, the conservation equation (8) gives as usual

$$\rho = \rho_0 a^{-q}, \quad q \equiv 3(w+1), \tag{13}$$

which after substitution in the Friedmann equation (11) yields (for $\mathcal{C} = 0$)

$$a(t) = \left[q m_0 t \left(1 + \frac{q}{2}\mu t \right) \right]^{1/q}, \tag{14}$$

where we have introduced the two mass scales

$$m_0 \equiv \frac{\kappa^2}{6}\rho_0, \qquad \mu \equiv \sqrt{-\Lambda/6}. \tag{15}$$

One sees that the solution for the scale factor interpolates between the low energy regime and the high energy regime and that the transition time is of the order of μ^{-1}, which is the characteristic mass scale associated with the cosmological constant.

Finally, the last term on the right hand side of (11) behaves like radiation and arises from the integration constant $\mathcal{C}$. This constant $\mathcal{C}$ is quite analogous to the Schwarzschild mass and it is related to the bulk Weyl tensor, which vanishes when $\mathcal{C} = 0$. In a cosmological context, this term is constrained to be small enough at the time of nucleosynthesis in order to satisfy the constraints on the number of extra light degrees of freedom.

The metric outside the brane can be also determined explicitly [3]. In the special case $\mathcal{C} = 0$, the metric has a very simple form and its components are given by

$$a(t,y) = a_0(t)\left(\cosh \mu y - \eta \sinh \mu|y|\right) \tag{16}$$

$$n(t,y) = \cosh \mu y - \tilde{\eta} \sinh \mu|y| \tag{17}$$

where

$$\eta = 1 + \frac{\rho}{\sigma}, \qquad \tilde{\eta} = \eta + \frac{\dot{\eta}}{H_0} \tag{18}$$

and we have chosen the time t corresponding to the cosmic time in the brane. The Randall-Sundrum model corresponds to $\rho = 0$, i.e. $\rho_b = \sigma$, which implies $\eta = \tilde{\eta} = 1$ and one recovers $a(t,y) = a_0 \exp(-\mu|y|)$.

As explained above, the Randall-Sundrum version of brane cosmology gives at sufficiently late times a cosmological evolution identical to usual four-dimensional cosmology. One must simply ensure that the low-energy regime encompasses the periods that are well constrained by cosmological observations. This essentially means that nucleosynthesis must take place in the low-energy regime. This is the case if the energy scale associated with the tension is higher than the nucleosynthesis energy scale, i.e.

$$\sigma^{1/4} \gtrsim 1 \text{ MeV}. \tag{19}$$

Combining this with (12) implies for the fundamental mass scale (defined by $\kappa^2 = M^{-3}$)

$$M \gtrsim 10^4 \text{ GeV}. \qquad \text{[nucleosynthesis]} \tag{20}$$

There is however another constraint, which is not of cosmological nature: the requirement to recover ordinary gravity down to scales of the submillimeter order, which have been probed by gravity experiments [8]. This implies

$$\ell = \mu^{-1} \lesssim 10^{-1} \text{ mm}, \tag{21}$$

which yields the constraint

$$M \gtrsim 10^8 \text{ GeV} \qquad \text{[gravity experiments]}. \tag{22}$$

The most stringent constraint is thus the latter, independent from cosmology. Even in the low-energy regime, there is an additional constraint restricting the range of values for the Weyl parameter $\mathcal{C}$. There are indeed bounds on the number of additional relativistic degrees of freedom allowed during nucleosynthesis (usually expressed as the number of additional light neutrino species). Typically, this gives the constraint

$$\frac{\rho_{Weyl}}{\rho_{rad}} \equiv \frac{\mathcal{C}\sigma}{2a^4\mu^2\rho} \lesssim 10\%. \tag{23}$$

So far, we have thus been able to build a model, which reproduces all qualitative and quantitative features of ordinary cosmology in the domains that have been tested by observations. The obvious next question is whether this will still hold for a more realistic cosmology that includes perturbations from homogeneity, and more interestingly, whether brane cosmology is capable of providing predictions that deviate from usual cosmology and which might tested in the future. A few elements are given in the next section but the main answer is still unkown.

3 Brane cosmological perturbations

Endowed with a viable homogeneous scenario, one would like to explore the much richer domain of cosmological perturbations and investigate whether brane cosmology leads to new effects that could be tested in the forthcoming cosmological observations, in particular of the anisotropies of the Cosmic Microwave Background.

Brane cosmological perturbations is a difficult subject and although there are now many published works on this question, no observational signature has yet been predicted. Below I will summarize some results concerning two differents aspects of perturbations. The first aspect deals with the evolution of scalar type perturbations on the brane, the second aspect with the production of gravitational waves from quantum fluctuations during a de Sitter phase in the brane.

Let us first discuss scalar type cosmological perturbations in brane cosmology. Choosing Gaussian normal coordinates, the metric with scalar perturbations can be written as [9,10]

$$ds^2 = -n^2(1+2A)dt^2 + 2n^2\partial_i B dt dx^i + a^2\left[(1+2C)\delta_{ij} + 2\partial_i\partial_j E\right]dx^i dx^j + dy^2, \tag{24}$$

where the perturbations at $y=0$ turn out to coincide exactly with the standard scalar cosmological perturbations. Using the compact notation $h_\alpha = \{A, B, C, E\}$ ($\alpha = 1, \ldots, 4$), the linearized Einstein equations

$$\delta G_{AB} + \Lambda \delta g_{AB} = \kappa^2 \delta T_{AB} \tag{25}$$

yield, *in the bulk*, expressions of the form

$$\delta G^{(5)}_{00} = \delta G^{st}_{00} + [h_\alpha, h'_\alpha, h''_\alpha] = -\Lambda \delta g_{00} \tag{26}$$

$$\delta G^{(5)}_{ij} = \delta G^{st}_{ij} + [h_\alpha, h'_\alpha, h''_\alpha] = -\Lambda \delta g_{ij} \tag{27}$$

$$\delta G^{(5)}_{0i} = \delta G^{st}_{0i} + [h_\alpha, h'_\alpha, h''_\alpha] = -\Lambda \delta g_{0i} \tag{28}$$

$$\delta G^{(5)}_{05} = [h_\alpha, h'_\alpha] = 0 \tag{29}$$

$$\delta G^{(5)}_{5i} = [h_\alpha, h'_\alpha] = 0 \tag{30}$$

$$\delta G^{(5)}_{55} = [h'_\alpha, h''_\alpha] = 0 \tag{31}$$

where the brackets stand for linear combinations of the perturbations and their derivatives. Brane matter enters only in the junction conditions, which at the linear level relate the first derivatives (with respect to y) of the metric perturbations h'_α to brane matter perturbations $\delta\rho$, δP, v, π. One can then substitute these relations back into the perturbed Einstein equations. $\delta G^{(5)}_{05} = 0$ then yields the usual perturbed energy conservation equation, whereas $\delta G^{(5)}_{i5} = 0$ yields the perturbed Euler equation. The other equations yield equations of motion for the perturbations where one recognizes the usual equations of motion in ordinary cosmology, but with two types of corrections [10]:

- modification of the homogeneous background coefficients due to the additional terms in the Friedmann equation. These corrections are negligible in the low energy regime $\rho \ll \sigma$. For long wavelength (larger than the Hubble scale) perturbations, one can thus obtain a transfer coefficient, $T = 5/6$, characterizing the high/low energy transition, i.e.

$$\Phi_{\rho\ll\sigma} = \frac{5}{6}\Phi_{\rho\gg\sigma}. \tag{32}$$

- presence of source terms in the equations. These terms come from the bulk perturbations and cannot be determined solely from the evolution inside the brane. To determine them, one must solve the full problem in the bulk (which also means to specify some initial conditions in the bulk). From the four-dimensial point of view, these terms from the fifth dimension appear like external source terms and their impact is formally similar to that of "active seeds", which have been studied in the context of topological defects.

Let us now discuss the origin of brane cosmological perturbations. In standard cosmology, the main mechanism for producing the cosmological perturbations is inflation. This can be generalized to brane cosmology, for instance via a scalar field confined in the brane[11]. While the scalar perturbations depend on the physical details of the inflationary model, gravitational waves are essentially sensitive only to the geometry and, in this sense, their predictions are more robust. Let us thus consider here the spectrum of gravitational waves generated during brane inflation[12].

To compute the production of gravitational waves, one can approximate slow-roll brane inflation by a succession of de Sitter phases. The metric for a de Sitter brane corresponds to a particular case of (17) with $\eta = \tilde{\eta}$ and can be written as

$$a(t,y) = a_0(t)\mathcal{A}(y), \quad n = \mathcal{A}(y), \quad \mathcal{A}(y) = \cosh\mu y - \left(1+\frac{\rho}{\sigma}\right)\sinh\mu|y|. \tag{33}$$

The gravitational waves appear in a perturbed metric of the form

$$ds^2 = -n^2dt^2 + a^2\left[\delta_{ij} + E^{TT}_{ij}\right]dx^i dx^j + dy^2, \tag{34}$$

where the 'TT' stands for transverse traceless. The linearized Einstein equations yield a wave equation for E^{TT}_{ij} that is separable. Writing $E_{ij} = \varphi_m(t)\mathcal{E}_m(y)\, e^{i\vec{k}.\vec{x}}\, e_{ij}$, where m stands for the mass (from the four-dimensional point of view), one finds that the time-dependent part must satisfy

$$\ddot{\varphi}_m + 3H_0\dot{\varphi}_m + \left[m^2 + \frac{k^2}{a_0^2}\right]\varphi_m = 0\,, \tag{35}$$

whereas the y-dependent part obeys

$$\mathcal{E}''_m + 4\frac{\mathcal{A}'}{\mathcal{A}}\mathcal{E}'_m + \frac{m^2}{\mathcal{A}^2}\mathcal{E}_m = 0\,. \tag{36}$$

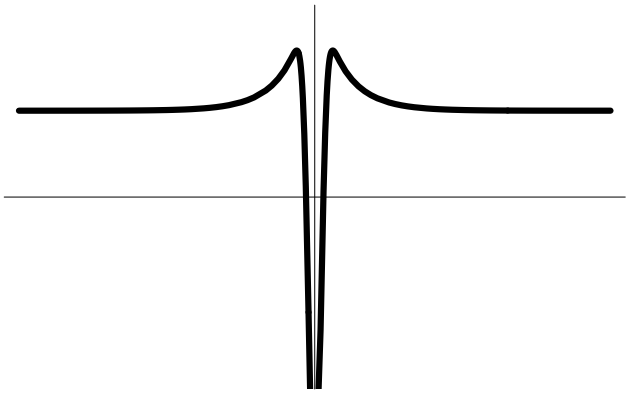

Figure 1: Potential for the gravitons

Like in the Minkowski case, the latter equation can be reformulated as a Schrödinger type equation,

$$\frac{d^2\Psi_m}{dz^2} - V(z)\Psi_m = -m^2\Psi_m\,, \tag{37}$$

after introducing the conformal coordinate $z = z_b + \int_0^y d\tilde{y}/\mathcal{A}(\tilde{y})$ (with $z_b = H_0^{-1}\sinh^{-1}(H_0/\mu)$) and defining $\Psi_m \equiv \mathcal{A}^{3/2}\mathcal{E}_m$. The potential is given by (see figure)

$$V(z) = \frac{15H_0^2}{4\sinh^2(H_0 z)} + \tfrac{9}{4}H_0^2 - 3\mu\left[1+\frac{\rho}{\sigma}\right]\delta(z-z_{\rm b})\,. \tag{38}$$

The non-zero value of the Hubble parameter implies the existence of a gap, $\Delta m = (3/2)H_0$, between the zero mode and the continuum of massive Kaluza-Klein modes. The latter will decay during the inflationary phase, according to (35), leaving of relevance only the zero mode. It is simply given by

$$\mathcal{E}_0 = C_1 \equiv \sqrt{\mu}\ F(H_0/\mu)\ , \tag{39}$$

where, imposing the normalization $2\int_{z_{\rm b}}^{\infty}|\Psi_0^2|dz = 1$, the constant C_1 has been expressed in terms of H_0 via the function

$$F(x) = \left\{\sqrt{1+x^2} - x^2\ln\left[\frac{1}{x}+\sqrt{1+\frac{1}{x^2}}\right]\right\}^{-1/2}. \tag{40}$$

Asymptotically, $F \simeq 1$ at low energies, i.e. $H_0 \ll \mu$, and $F \simeq \sqrt{3H_0/(2\mu)}$ at high energies, i.e. $H_0 \gg \mu$. One can then evaluate the vacuum quantum fluctuations of the zero mode by using the standard canonical quantization. To do this explicitly, one writes the five-dimensional action for gravity at second order in the perturbations. Keeping only the zero mode and integrating over the fifth dimension, one obtains

$$S_{\rm g} = \frac{1}{8\kappa^2}\sum_{+,\times}\int d\eta\, d^3\vec{k}\, a_o^2\left[\left(\frac{d\varphi_o}{d\eta}\right)^2 + k^2{\varphi_o}^2\right], \tag{41}$$

This has the standard form for a massless graviton in four-dimensional cosmology, apart from the overall factor $1/8\kappa^2$ instead of $1/8\kappa_4^2$. It follows that quantum fluctuations in each polarization, φ_o, have an amplitude of $2\kappa(H_o/2\pi)$ on super-horizon scales. Quantum fluctuations on the brane at $y = 0$, where $E_o = C_1\varphi_0$, thus have the typical amplitude

$$\frac{1}{2\kappa_4}\delta E_{\rm brane} = \left(\frac{H_0}{2\pi}\right)F(H_0/\mu) \tag{42}$$

At low energies, $F \simeq 1$ and one recovers exactly the usual four-dimensional result but at higher energies the multiplicative factor F provides an *enhancement of the gravitational wave spectrum amplitude with respect to the four-dimensional result*. An open question is how the gravitational waves will evolve during the subsequent cosmological phases, the radiation and matter eras.

4 Conclusions

The idea of extra-dimensions hidden because ordinary matter/fields have not access to them has been very actively explored lately. We have presented here the simplest version of a cosmological scenario inspired by this idea. At the level of homogeneous cosmology, the scenario seems so far consistent with observations since it deviates from standard cosmology only in the far past of the universe, for energy scales $\rho^{1/4} \gtrsim 10^3$ GeV, i.e. well before nucleosynthesis. Brane cosmological perturbations is a much more difficult question since one must take into account the propagation of gravitational waves in the bulk.
